ELEVATION CORRECTION TABLES FOR BAROMETRIC PRESSURE SENSORS

INTRODUCTION

Weather stations located at elevations above sea level often need adjustment to the barometer so that sea level pressure is the indicated value. Sometimes the information necessary making for the adjustment is unavailable or is difficult to obtain. This document provides tables that give the barometer corrections for various elevations. A brief discussion of the concept of pressure variations with elevation is also included.

USING THE TABLES

Barometer corrections to sea level pressure are most often associated with airports, television reports, or National Weather Service offices. These organizations give sea level reduced pressure readings. Some large organizations may have networks of weather stations spread over a large region to measure lateral variations in pressure such as those produced by weather fronts. It is not necessary for a barometer to be corrected to sea level in order for it to operate. The correction adjustment is simply a preference for the way that pressure is reported.

Barometric pressure corrections can be obtained by contacting a local airport or National Weather Service weather station operator and requesting the current local reading. The barometer in question is then adjusted so that its reading matches that obtained from the airport or NWS. Some error will be introduced using this method of adjustment, increasing with distance since lateral pressure variations may increase with the horizontal distance from the reporting weather station.

The tables provided with this document are based upon the United States Standard Atmosphere and can be used in situations where no reporting stations exist within the immediate area. The tables give the correction factor that is added to the barometric pressure reading for a given station elevation. The correction is given both in inches of mercury (inHg) and in millibars (mb). Values are indicated for elevations expressed in feet above sea level.

For any station elevation, add the “**deviation from zero**” figure to the barometer’s current barometric pressure reading.

As an example, consider a barometer located at an elevation of 4550 feet with a current reading of 25.07 inHg. Using the tables, a value of 4.60 inHg should be added to the reading. The barometer should be adjusted until it produces a reading of 29.67 inHg to report the equivalent sea level pressure.

The “**standard pressure**” figures indicate the calculated barometric pressure at each elevation based upon the United States Standard Atmosphere. Actual pressures typically vary by up to 1 inHg (34 mb), depending upon weather conditions, time of year, and time of day. The variation is seldom more than 2 inHg (68 mb) from the values given, even in a severe storm. These figures provide a method for checking a barometer’s operation. A barometer that is located at an elevation of 1950 feet and is reporting a pressure of 860 mb has a calibration problem or is sitting in the eye of a super hurricane!

STANDARD PRESSURE VS. ELEVATION

Feet and mb
